The influence of purchase goal and personality variables, on customers’ preference to online information sources / Alon Abramovitz

Abstract

The recent development of the Internet and its becoming an interactive tool enables surfers to be more active and express their views about various aspects. The various sites in the web enable whoever logs in to respond, write and be active. An example for that are the news sites, where those interested are able to express their opinions about published article as part of this revolution, it is also possible to transfer information among surfers, which was not possible at the beginning of the Internet (Web 1). Another example is transferring information among consumers via the Internet about various products and services. In the past the consumers transferred information by word of mouth, which helped in reaching a decision about purchasing some product or service. Nowadays the consumers can reach greater information with no geographical limit and even receive information from people with whom they have no connection, beside the fact that they are interested in the same product. Consumers can check information and recommendations in the Internet and then purchase the products online or in the stores. It is possible to find a lot of information in the web about various products and services, such as books, music, movies, food and restaurants, computers, medicine, hotels etc.

Research differentiates two kinds of purchases: Purchase for pleasure, i.e. enjoyment (enjoying the product and the process of purchasing), and purchase for utilitarian purpose (need for the product in order to perform a mission and the purchasing process as the mission to be performed). There are products with a more hedonistic value, such as purchasing movies and some more utilitarian, like purchasing food. One product can contain both possibilities, utilitarian and hedonistic. A book, for example, can be with a utilitarian purpose, such as various manuals, and can be for hedonistic purpose, such as stories.

This paper is composed of a quantitative and qualitative research and examines consumers' behavior and their relying on information about tourism. The level of relying on Internet information before purchasing some product or service may differ from one person to another and per the type of product or service. The quantitative research in this paper examines the level of hedonism and decision making process of
information seekers. The type of information was also examined, information given by experts in the field (positive and negative) as compared to information given by surfers (positive and negative) about the product and presented as having an hedonistic purpose as compared to a product with a utilitarian purpose.

The qualitative research is used as a tool for deeper understanding of the quantitative research. This part of the paper examines why consumers do what they are doing. That is, why do they choose to use certain information and what is their need to determine the validity of information they receive. In addition, there is an attempt to understand the importance of the goal of purchase and the decision-making process before purchase.

The quantitative research assumption is that there is a connection between the consumer's hedonistic level and decision-making process and the information he will rely on when deciding to make a purchase. There will also be a difference between the decision-making process when the purpose is utilitarian and when it is hedonistic.

The qualitative research assumption was that the consumers will choose to rely on a certain source of information according to its reliability and previous acquaintance with the source of information.

As part of the quantitative research, four websites were formed. Each site contained questionnaires examining the subjects' hedonistic level and his decision-making process.

They also supplied the possibility to purchase hotel services. Each of the four websites included a hotel, when the purpose of purchasing was different from one site to another. Two sites were with utilitarian goal and the difference was the order of responses. In the first questionnaire, the surfers' responses were positive and in the second questionnaire the tourism critics' responses were positive. In the two other sites the purpose was hedonistic and the difference also was in the order of responses.

The subjects answered the questionnaires and decided if to purchase service from the hotel based on the information presented (positive and negative information by experts, tourism critics as opposed to surfers' positive and negative information).

Links to sites were divided between 260 subjects, adult women and males over the age of 21. Link to the sites was distributed in forums dealing with tourism, Facebook tourism groups and students.
The qualitative research was based on interviews with 20 subjects, adult Israeli women and males over the age of 21, who surf the Internet several hours per day and order hotel rooms.

As part of the qualitative research there is a presentation simulating Internet surfing. While surfing, the interviewees were required to make decisions about reserving a room. While surfing the interviewees were asked questions that are half-constructed in-depth interview. The presentation included three categories of hotels. When the subject chose one category of hotels where he is used to reserve a room, he was presented with three sources of information. The subject chose the sources of information he would like to read. After reading each information source, he was asked questions regarding several measures of the source: such as the source reliability, contents, identity of person recommending the hotel etc. Finally the subject was required to decide if he is reserving a room and what kind of information he will base his decision on.

The quantitative research findings showed that there is consumers preference to rely on surfers recommendations more than tourism critics ones. Consumers conceive the surfers as more reliable, especially when their reactions are negative; negative responses are conceived as stronger than positive ones. When adding the personal variables and the purpose of purchase, it seems that when the consumer level of hedonism is higher and the purchase purpose is hedonistic, there is high willingness to reserve a hotel room. On the other hand, when the level of hedonism is low, the willingness to be in a hotel was higher when the purpose was utilitarian. As opposed to the research assumption, there was no difference in relying on a certain source of information when the level of hedonism and purpose of purchase are changing. A consumer with high level of hedonism might act like a consumer with a low level when choosing the source of information to rely on. A consumer reserving a hotel room for utilitarian purpose (convention) may rely on the same source as the consumer with a hedonistic purpose (holiday).

The qualitative research findings point on the fact that each source of information was critically examined by the subjects. The interviewees sort the information by criteria helping them increase the information reliability. Extreme reactions are conceived as unreliable, for example. It is possible to examine the information given by surfers who visited the hotel in the past per many criteria and maybe this is why the interviewees relied mainly on this source when making a decision. In addition, the
most important criteria are the location of the hotel and its cleanliness and the importance is changing according to the purpose of purchase. The criteria of hotel facilities will be more important when the goal is a holiday - when the consumer spends most of his time in the hotel and uses the facilities - than a hotel reserved for a trip in a new city, because the consumer doesn't stay there a long time. In order to make a decision, there is a need for at least two sources of information. After reading the first source, the consumer makes assumptions that are verified or denied by the additional sources. Information repeated in various sources is conceived as more reliable and there is a comparison of several hotels in the same price range. An especially cheap price (sale) may change a decision even if the important criteria marks were not high.

The research results contribute to the understanding of consumers' behavior when reading information in the Internet. They might assist companies interested to market their products via the Internet. A consumer examining the information received per the criteria presented in this paper may increase the level of reliability of this information. On the scientific side, the paper contributes and adds to existing research about consumers' recommendation on the web. The variables of purchase purpose and subjects personalities were not examined at all or very little examined in the context of Internet recommendations influence on consumers looking for information. In addition, this is the first integrated quantitative and qualitative research in this area.
